AI ENGINEER WORK INTERVIEW

Enterprise procurement is painfully slow.

When a company is trying to become an approved vendor, it may need to complete security, privacy, legal, financial, compliance, and AI-risk reviews. Requirements differ between customers and are often scattered across questionnaires, documents, emails, portals, and conversations.

The answers are similarly fragmented across internal documentation and people. Information may be missing, outdated, contradictory, or require verification before it can safely be shared externally.

> **The problem: Teams spend significant time figuring out what a customer requires, what is already known, what is missing, who can resolve it, what is blocking progress, and what should happen next.**
>
> **Build a system that helps a company navigate this process and move procurement forward faster.**

Your scenario

You have been given a working folder from one in-progress enterprise procurement case involving a technology supplier and a prospective customer. It contains customer correspondence, lengthy questionnaires, internal conversations, technical material, evidence, notes, and other artifacts. There is no authoritative checklist, and some sources may be incomplete, stale, duplicated, contradictory, or irrelevant.

Use this case to build and demonstrate your solution. Your prototype does not need to support every possible procurement process within two days, but we are interested in how your approach could extend to customers with different requirements, documents, processes, and stakeholders.

Expected final result

By the end of the two days, deliver a **working prototype** that demonstrates a meaningful improvement to the supplied procurement process. At minimum, someone using it should be able to understand **(1) what is required, (2) what is already known or supported by evidence, (3) what remains unresolved, (4) what is blocking progress, and (5) what should happen next.**

You are not expected to complete every questionnaire or solve procurement end-to-end. Scope the problem appropriately. Your system should do more than summarize the folder: demonstrate how your approach turns messy, changing information into useful progress. Where information is uncertain or contradictory, handle that explicitly rather than inventing an answer.

Questions & domain context

If you have questions about how procurement is currently handled manually, ask Jai. You may use him as a domain resource to understand the existing process, where time is being spent, how information is gathered, who is typically involved, and where the current workflow breaks down. You are responsible for deciding what questions are useful and how that information should influence your solution.

Final demo

Demo the prototype on the provided case. Show how it arrives at its understanding, how it handles missing or conflicting information, and how new information would affect the result. Explain your architecture, what you automated versus kept deterministic or human-reviewed, your tradeoffs, and how the approach would adapt to a substantially different procurement case.

Constraints

You have two days. There is no prescribed product, UI, workflow, agent architecture, model, or framework. Optimize for usefulness, technical depth, reliability, adaptability, and sound judgment rather than polish.

We are evaluating: problem framing, ability to learn an unfamiliar domain, AI/LLM depth, system design, technical execution, **creativity and cleverness of the solution design**, judgment under ambiguity, reliability, adaptability, and the quality of your tradeoffs.
